

Deep Learning in sequencing data analysis

2019 Dragon Star Bioinformatics Course (Day 5)

Background

Machine Learning

Deep learning (also known as **deep structured learning** or **hierarchical learning**) is part of a broader family of **machine learning** methods based on artificial neural networks. Learning can be **supervised**, **semi-supervised** or **unsupervised**.^{[1][2][3]}

Deep learning architectures such as **deep neural networks**, **deep belief networks**, **recurrent neural networks** and **convolutional neural networks** have been applied to fields including **computer vision**, **speech recognition**, **natural language processing**, **audio recognition**, **social network filtering**, **machine translation**, **bioinformatics**, **drug design**, **medical image analysis**, **material inspection** and **board game programs**, where they have produced results comparable to and in some cases superior to human experts.^{[4][5][6]}

Artificial Neural Networks (ANNs) were inspired by information processing and distributed communication nodes in biological systems. ANNs have various differences from biological **brains**. Specifically, neural networks tend to be static and symbolic, while the biological brain of most living organisms is dynamic (plastic) and analog.^{[7][8][9]}

Speech
recognition

Text topics

Build a model based on known data
Rely on patterns and inference
Make predictions to perform tasks like human

Traditional machine learning

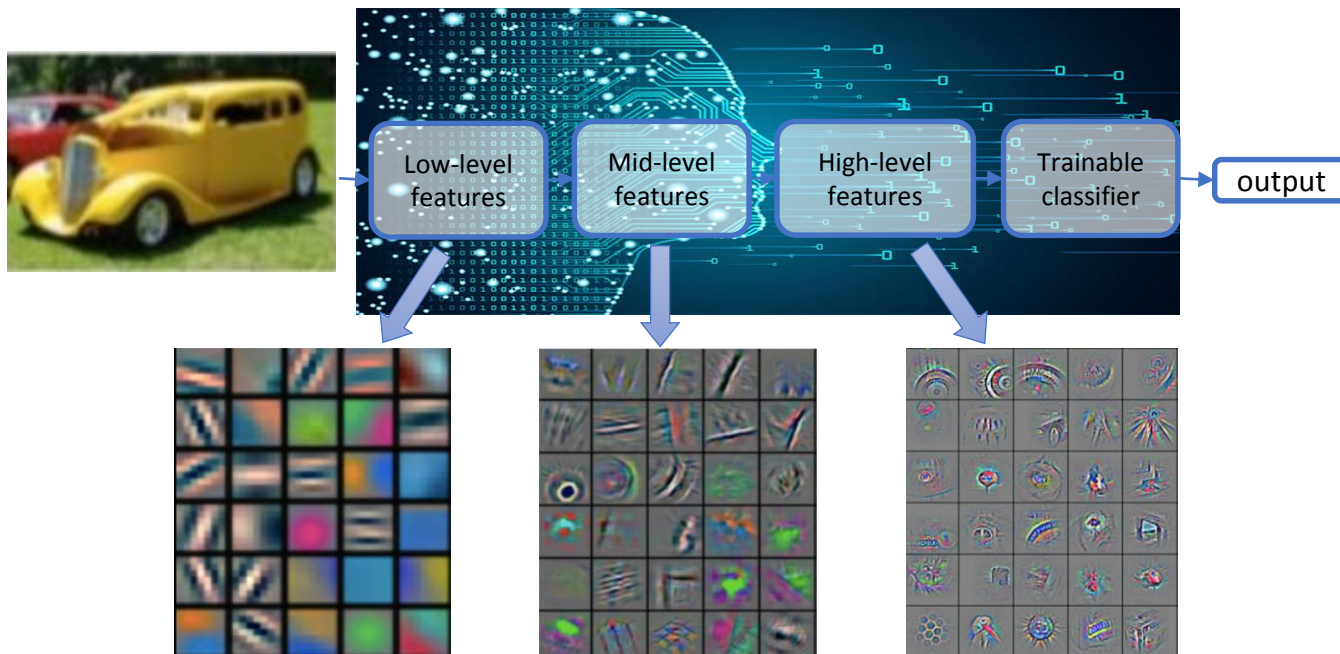

- Traditional machine learning models use hand-crafted features and relatively simple trainable classifier.

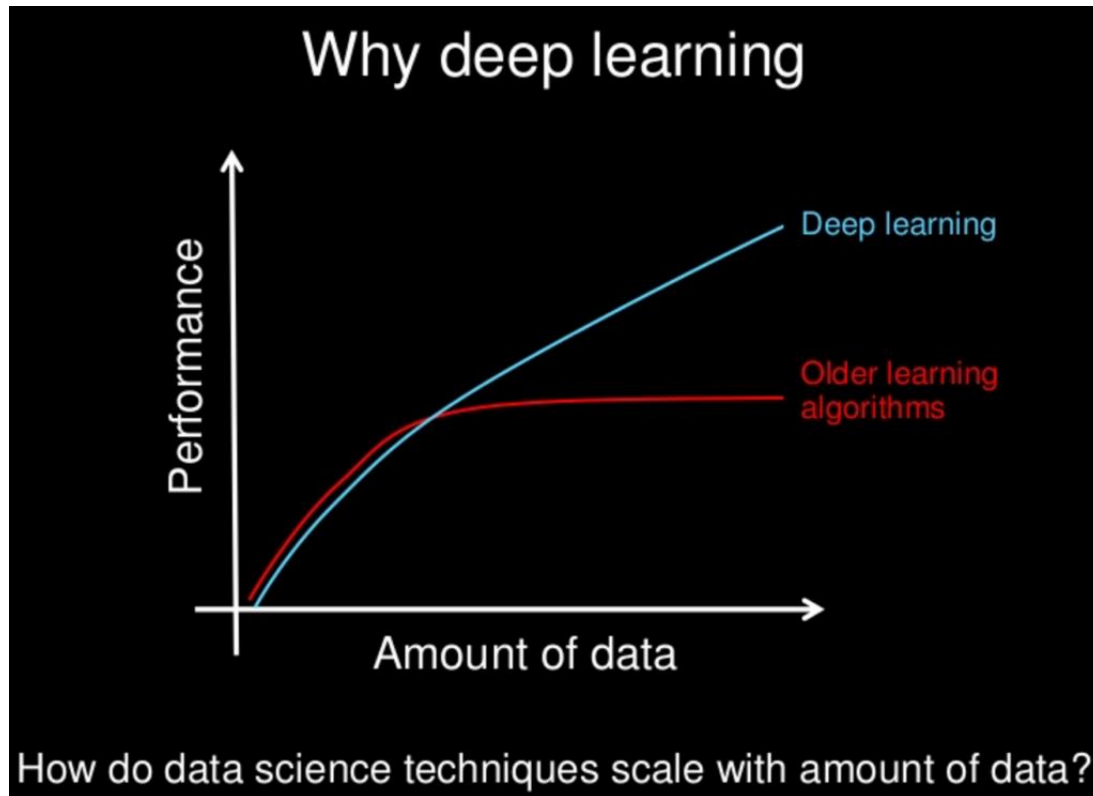

- This approach has the following limitations:
 - It is very tedious and costly to develop hand-crafted features
 - The hand-crafted features are usually highly dependent on one application, and cannot be transferred easily to other applications

Deep learning

- Deep learning (a.k.a. representation learning) seeks to learn rich hierarchical representations (i.e. features) automatically through multiple stage of feature learning process.

Background – deep learning

Deep learning

- Deep learning
 - Supervised, semi-supervised, and unsupervised
- Types of deep learning frameworks:
 - deep neural networks, deep belief networks, recurrent neural networks and so on
- Use a cascade of multiple layers of nonlinear processing units for feature extraction and transformation
 - Each successive layer uses the output from the previous layer as input.
- Learn multiple levels of representations
 - Correspond to different levels of abstraction
 - The levels form a hierarchy of concepts.

Deep neural network

Simple Neural Network

● Input Layer

Deep Learning Neural Network

● Hidden Layer

● Output Layer

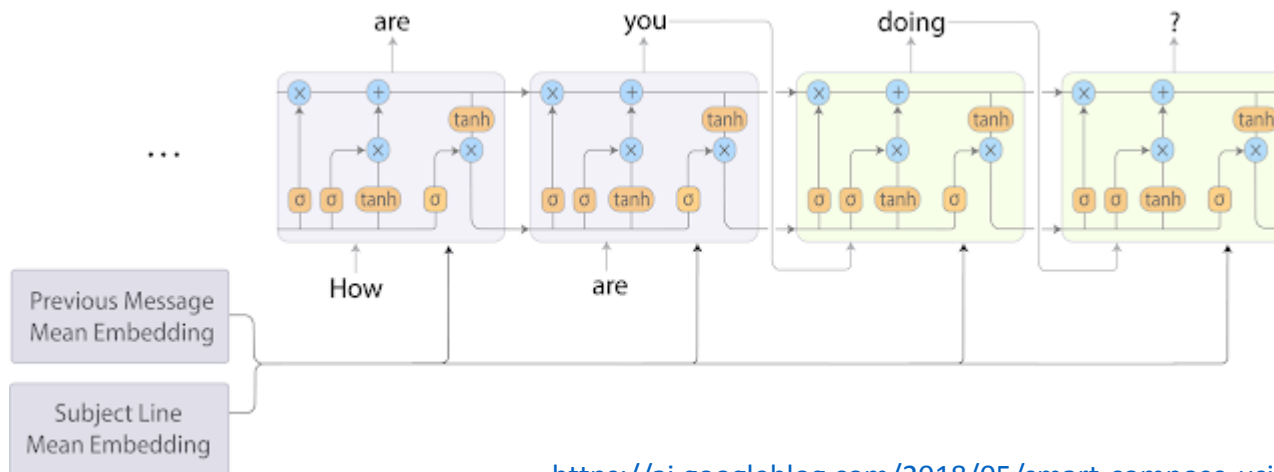

Recurrent neural network (RNN)

- Types of RNN

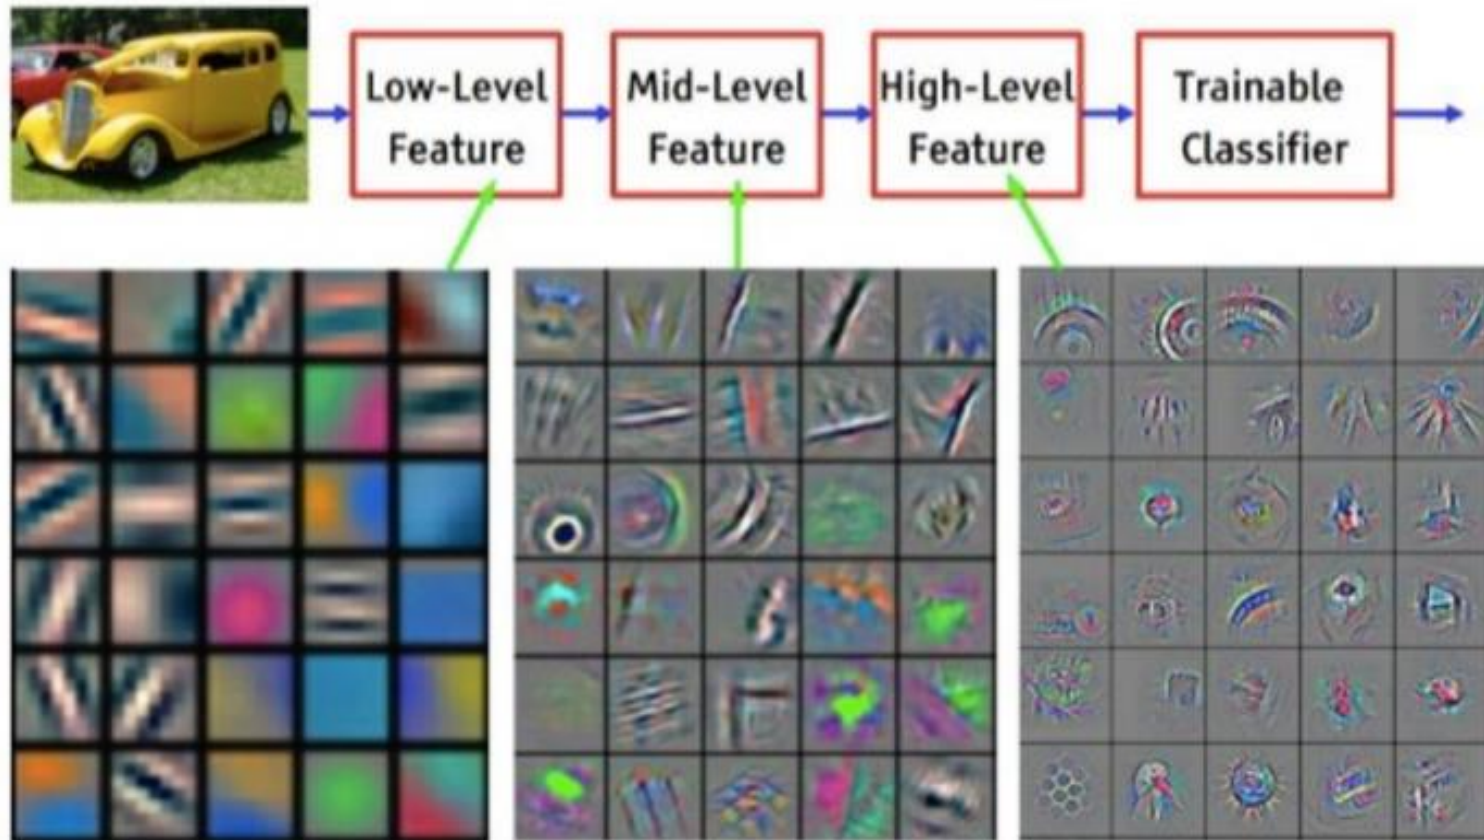

- Forward RNN
- Bidirectional RNN

- Cell types in RNN

- LSTM --- long short-term memory cell
- GRU --- gated recurrent unit

Convolutional neural network (CNN)

Multiple convolution layers in CNN

Convolutional Neural Networks

- Convolution

1x1	1x0	1x1	0	0
0x0	1x1	1x0	1	0
0x1	0x0	1x1	1	1
0	0	1	1	0
0	1	1	0	0

Convolutional Neural Networks

- An example

Typical CNN model

Chiron for Nanopore base calling

- Translating nanopore raw signal directly into nucleotide sequence using deep learning
- A novel architecture that couples a convolutional neural network (CNN) with an RNN

Examples of Chiron base calling

- Visualization of the predicted probability of bases and the readout sequence

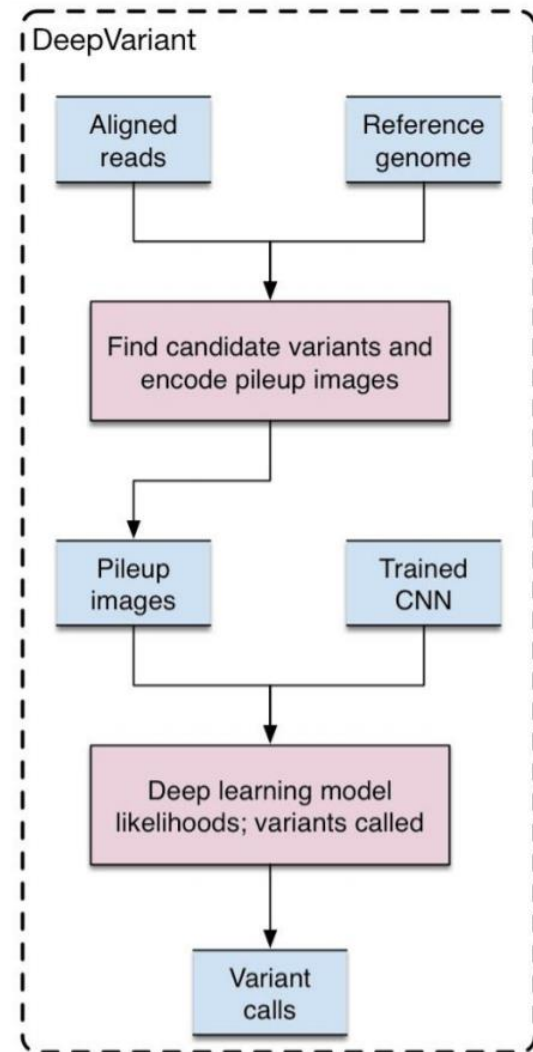

DeepVariant for variant calling

- A deep convolutional neural network to call genetic variation in aligned sequencing reads.
 - 1. DeepVariant begins by finding SNPs and indels in reads aligned to the reference genome.
 - Candidate sites chosen with high sensitivity but low specificity.
 - Criteria includes read depth, alternative allele frequencies and base qualities.
 - 2. Pileup image of reference and read data around each candidate site is created.
 - 3. Using adaptation of deep learning
 - 4. Pileup images and emits probabilities for each of the three diploid genotypes (hom-ref, hom-alt, het) at the candidate site
- Advantages:
 - Learned model generalizes across genome builds and mammalian species.
 - Call variants in a variety of sequencing technologies and experimental designs, from deep whole genomes to Ion Ampliseq exomes

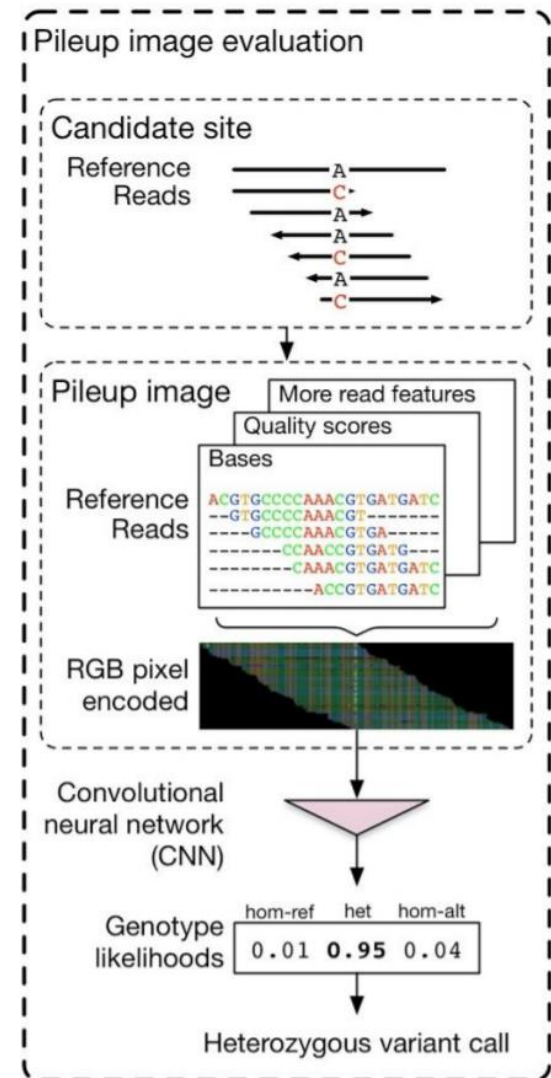

DeepVariant: Workflow

- The input
 - A BAM file after alignment
 - A reference genome in a FASTA file
- The output
 - Variant calls saved in a VCF file format.

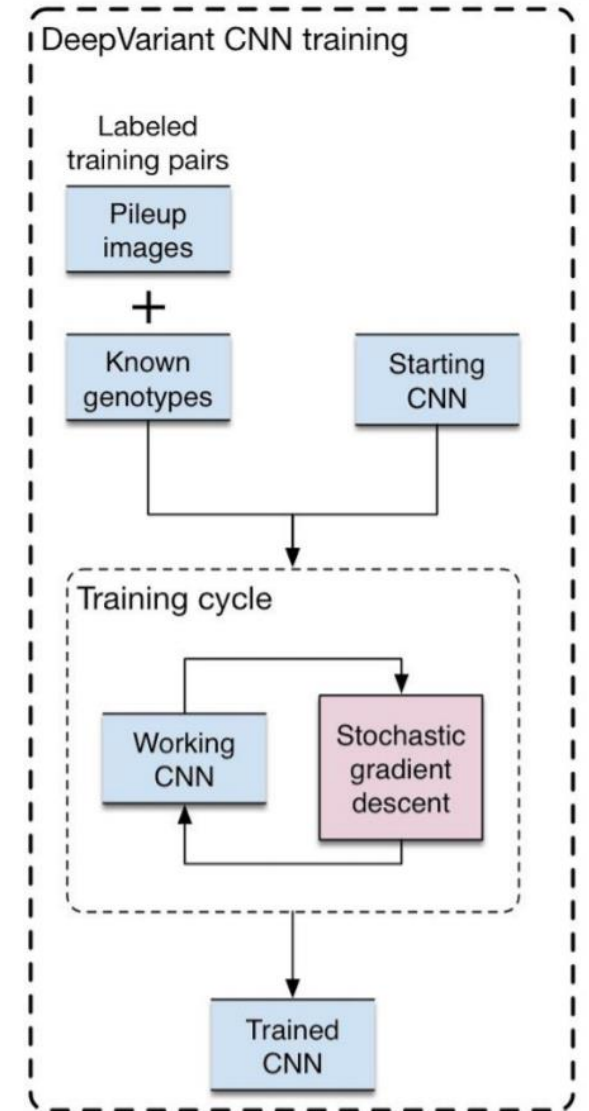

DeepVariant: Workflow

- How to create the pileup images.
 - First row stores reference sequence information
 - Following rows store information about each individual read.
- Each pileup image is an RGB channel image.
 - Red channel encodes each base by a different color.
 - Green channel encodes the base quality.
 - Blue channel encodes if the read is on positive strand or not. Reference rows are positive by default.

DeepVariant: Workflow

- In a training process:
 - Inputs are pileup images and known genotypes
 - Model is updated after each cycle using stochastic gradient descent

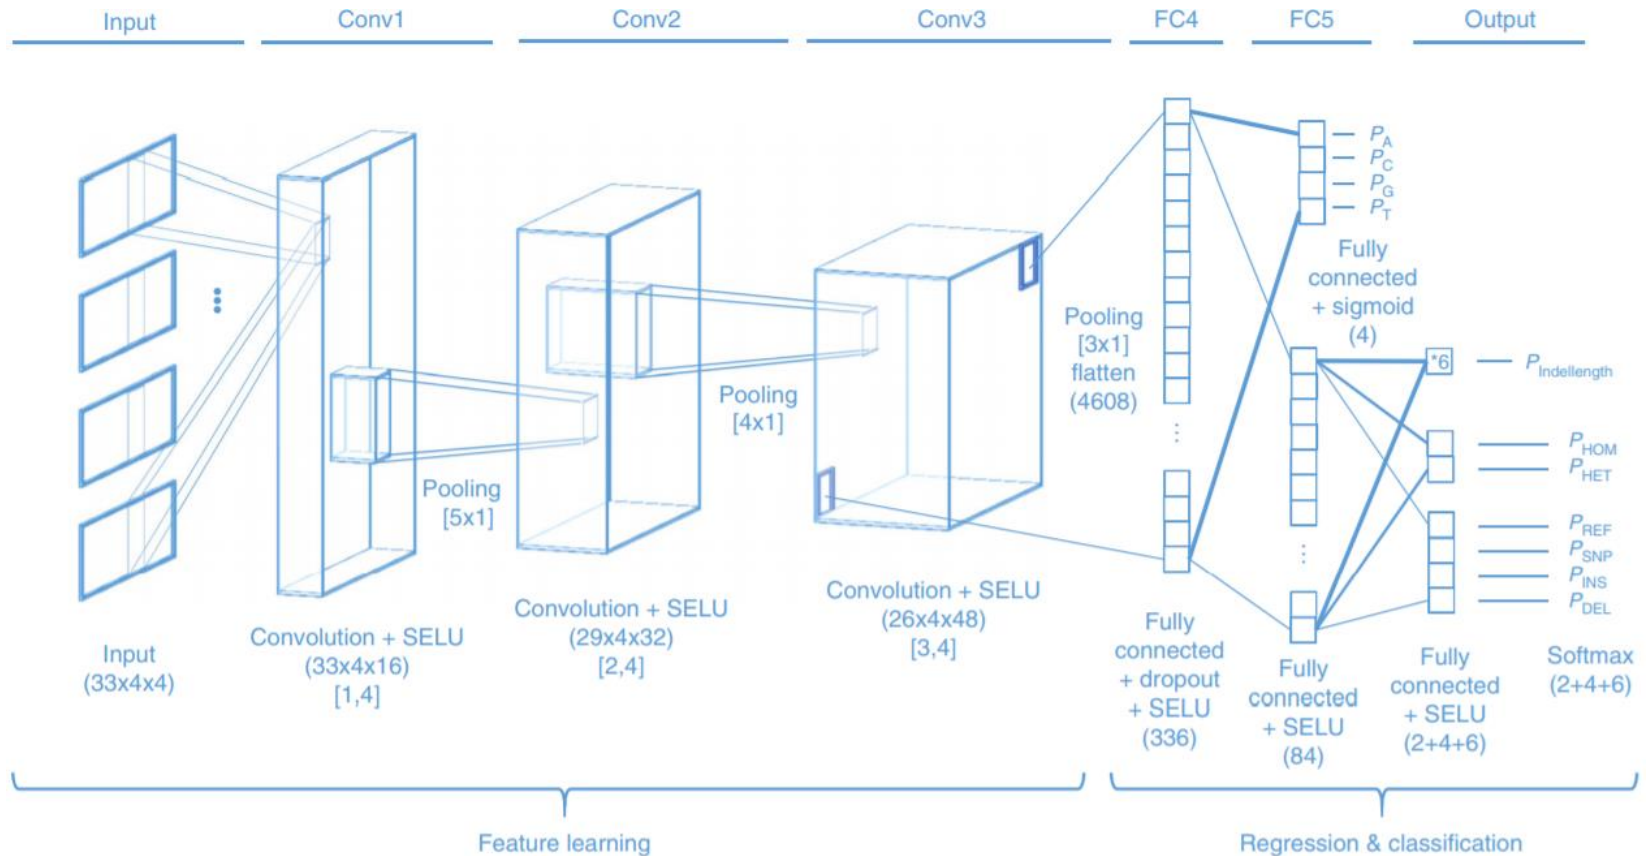

DeepVariant: Performance

Concluding remarks

- Traditional data mining and machine learning approaches require feature engineering from data, and then build prediction models.
- Deep learning provides new paradigms to extract learning models directly from complex data.
- Deep learning approaches will play important roles in human genomics research, such as sequencing data analysis, variant interpretation and precision health.
